

Attention Map Comparison

Visual comparison of model attention under varying spatial contextual richness.

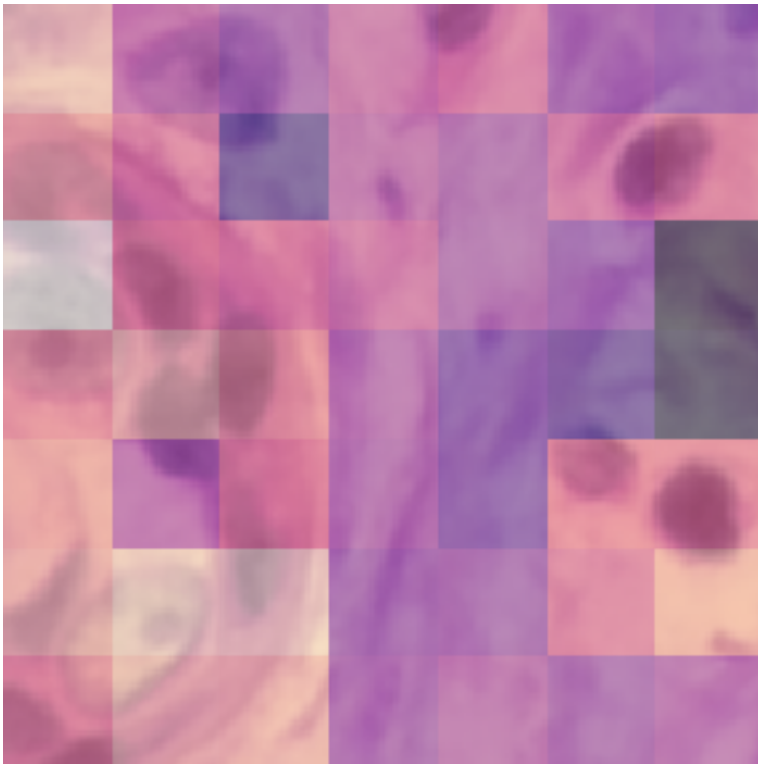

100px Patch

Full spatial context

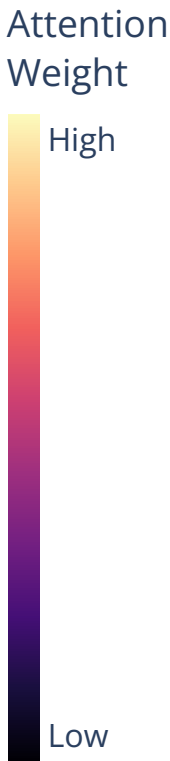

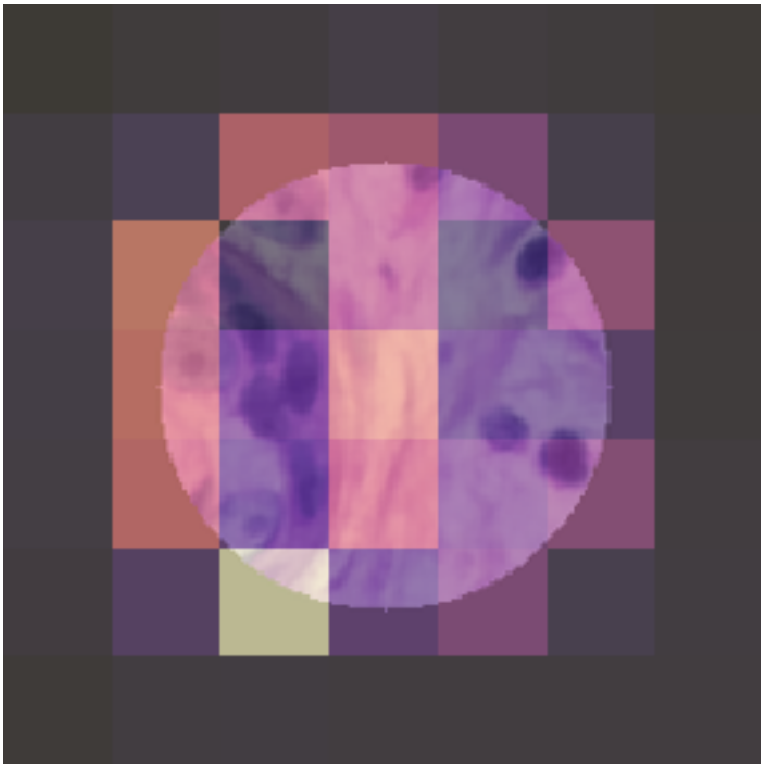

50px Patch

Reduced spatial context

Masked Patch

Local morphology only

Interpreting the Attention Maps

Attention maps provide a qualitative indication of which image regions contributed most strongly to model predictions under each spatial context condition.

Comparing attention distributions across the 100px, 50px, and masked inputs allows assessment of whether the model relies primarily on local nuclear morphology or broader tissue-level architecture.

Attention maps provide qualitative interpretability only and should not be treated as definitive mechanistic explanations of model decision-making.
